Supplementary material for Bandit Learning in Concave N-Person Games

Anonymous Author(s) Affiliation Address email

¹ A Preamble

- ² For completeness, we briefly reproduce here some basic definitions concerning the most important ³ elements of our paper.
- 4 First, given a K-strongly convex regularizer $h: \mathcal{X} \to \mathbb{R}$ (the player index i is suppressed for
- ⁵ simplicity), the associated Bregman divergence is defined as

$$
D(p, x) = h(p) - h(x) - \langle \nabla h(x), p - x \rangle
$$
\n(A.1)

6 with $\nabla h(x)$ denoting a continuous selection of $\partial h(x)$. The induced prox-mapping is then given by

$$
P_x(y) = \underset{x' \in \mathcal{X}}{\arg \min} \{ \langle y, x - x' \rangle + D(x', x) \}
$$

=
$$
\underset{x' \in \mathcal{X}}{\arg \max} \{ \langle y + \nabla h(x), x' \rangle - h(x') \}
$$
 (A.2)

- and is defined for all $x \in \text{dom } \partial h$, $y \in \mathcal{Y}$ (recall here that $\mathcal{Y} \equiv \mathcal{V}^*$ denotes the dual of the ambient vector space V in which the game's action space X is embedded).^{[1](#page-0-0)} 8
- ⁹ With all this at hand, the multi-agent mirror descent algorithm with bandit feedback is defined as ¹⁰ follows:

$$
\hat{X}_n = X_n + \delta_n W_n,
$$

\n
$$
X_{n+1} = P_{X_n}(\gamma_n \hat{v}_n).
$$
\n(MD-b)

11 where the perturbation W_n and the estimate \hat{v}_n are given respectively by

$$
W_{i,n} = Z_{i,n} - r_i^{-1}(X_{i,n} - p_i) \qquad \hat{v}_{i,n} = (d_i/\delta_n)u_i(\hat{X}_n) Z_{i,n}.
$$
 (A.3)

- 12 In the above, the query directions $Z_{i,n}$ are drawn independently and uniformly across players at each
- is stage n from the corresponding unit sphere; finally, $\mathbb{B}_{r_i}(p_i)$ denotes a ball that is entirely contained ia in \mathcal{X}_i . For a schematic representation, see also [Fig. 1.](#page-1-0)

¹⁵ B Monotone games

¹⁶ We now turn to the game-theoretic examples of Section 2. Before studying them in detail, it will be

- ¹⁷ convenient to introduce a straightforward second-order test for monotonicity based on the game's ¹⁸ Hessian matrix.
- ¹⁹ Specifically, extending the notion of the Hessian of an ordinary (scalar) function, the (λ*-weighted*) 20 *Hessian* of a game G is defined as the block matrix $H_G(x; \lambda) = (H_{ij}(x; \lambda))_{i,j \in \mathcal{N}}$ with blocks

$$
H_{ij}(x; \lambda) = \frac{\lambda_i}{2} \nabla_j \nabla_i u_i(x) + \frac{\lambda_j}{2} (\nabla_i \nabla_j u_j(x))^\top.
$$
 (B.1)

Submitted to 32nd Conference on Neural Information Processing Systems (NeurIPS 2018). Do not distribute.

¹We also recall here that Y comes naturally equipped with the dual norm $||y||_* = \max\{|\langle y, x \rangle | : ||x|| \le 1\}.$

Figure 1: Schematic representation of [\(MD-b\)](#page-0-1) with ordinary, Euclidean projections. To reduce visual clutter, we did not include the feasibility adjustment $r^{-1}(x-p)$ in the action selection step $X_n \mapsto \hat{X}_n$.

21 As was shown by [Rosen](#page-9-0) [\(1965,](#page-9-0) Theorem 6), G satisifes [\(DSC\)](#page-0-2) with weight vector λ whenever $z^{\top}H_{\mathcal{G}}(x;\lambda)z < 0$ for all $x \in \mathcal{X}$ and all nonzero $z \in \mathcal{V} \equiv \prod_{i} \mathcal{V}_i$ that are tangent to \mathcal{X} at x^2 x^2 It is 23 thus common to check for monotonicity by taking $\lambda_i = 1$ for all $i \in \mathcal{N}$ and verifying whether the 24 unweighted Hessian of G is negative-definite on the affine hull of X .

²⁵ Cournot competition (Example [2.1\)](#page-0-2). In the standard Cournot oligopoly model described in the ²⁶ main body of the paper, the players' payoff functions are given by

$$
u_i(x) = x_i \left(a - b \sum_j x_j \right) - c_i x_i. \tag{B.2}
$$

²⁷ Consequently, a simple differentiation yields

$$
H_{ij}(x) = \frac{1}{2} \frac{\partial^2 u_i}{\partial x_i \partial x_j} + \frac{1}{2} \frac{\partial^2 u_j}{\partial x_j \partial x_i} = -b(1 + \delta_{ij}),
$$
(B.3)

- 28 where $\delta_{ij} = 1 \{i = j\}$ is the Kronecker delta. This matrix is clearly negative-definite, so the game is ²⁹ monotone.
- 30 Resource allocation auctions (Example [2.2\)](#page-0-2). In our auction-theoretic example, the players' payoff ³¹ functions are given by

$$
u_i(x_i; x_{-i}) = \sum_{s \in \mathcal{S}} \left[\frac{g_i q_s x_{is}}{c_s + \sum_{j \in \mathcal{N}} x_{js}} - x_{is} \right]
$$
(B.4)

- ³² To prove monotonicity in this example, we will consider the following criterion due to [Goodman](#page-9-1) 33 [\(1980\)](#page-9-1): a game G satisfies [\(DSC\)](#page-0-2) with weights λ_i , $i \in \mathcal{N}$, if:
- *a*) Each payoff function u_i is strictly concave in x_i and convex in x_{-i} .
- 35 *b*) The function $\sum_{i \in \mathcal{N}} \lambda_i u_i(x)$ is concave in x.
- 36 Since the function $\phi(x) = x/(c + x)$ is strictly concave in x for all $c > 0$, the first condition above is 37 trivial to verify. For the second, letting $\lambda_i = 1/g_i$ gives

$$
\sum_{i \in \mathcal{N}} \lambda_i u_i(x) = \sum_{i \in \mathcal{N}} \sum_{s \in \mathcal{S}} \frac{q_s x_{is}}{c_s + \sum_{j \in \mathcal{N}} x_{js}} - \sum_{i \in \mathcal{N}} \sum_{s \in \mathcal{S}} x_{is}
$$
\n
$$
= \sum_{s \in \mathcal{S}} q_s \frac{\sum_{i \in \mathcal{N}} x_{is}}{c_s + \sum_{i \in \mathcal{N}} x_{is}} - \sum_{i \in \mathcal{N}} \sum_{s \in \mathcal{S}} x_{is}.
$$
\n(B.5)

³⁸ Since the summands above are all concave in their respective arguments, our claim follows.

²By "tangent" we mean here that z belongs to the tangent cone $TC(x)$ to X at x, i.e., the intersection of all supporting (closed) half-spaces of X at x .

³⁹ C Properties of Bregman proximal mappings

⁴⁰ In this appendix, we provide some auxiliary results and estimates that are used throughout the ⁴¹ convergence analysis of [Appendix D.](#page-3-0) Some of the results we present here are not new (see e.g.,

⁴² [Nemirovski et al.,](#page-9-2) [2009\)](#page-9-2); however, the set of hypotheses used to obtain them varies widely in the

- ⁴³ literature, so we provide all proofs for completeness.
- 44 In what follows, we will make frequent use of the convex conjugate $h^*: \mathcal{Y} \to \mathbb{R}$ of h, defined here as

$$
h^*(y) = \max_{x \in \mathcal{X}} \{ \langle y, x \rangle - h(x) \}. \tag{C.1}
$$

- 45 By standard results in convex analysis [\(Rockafellar,](#page-9-3) [1970,](#page-9-3) Chap. 26), h^* is differentiable on $\mathcal Y$ and
- ⁴⁶ its gradient satisfies the identity

$$
\nabla h^*(y) = \underset{x \in \mathcal{X}}{\text{arg max}} \{ \langle y, x \rangle - h(x) \}. \tag{C.2}
$$

⁴⁷ For notational convenience, we will also write

$$
Q(y) = \nabla h^*(y) \tag{C.3}
$$

- 48 and we will refer to $Q: \mathcal{Y} \to \mathcal{X}$ as the *mirror map* generated by h.
- 49 Together with the prox-mapping induced by h , all these notions are related as follows:
- 50 **Lemma 1.** *Let h be a regularizer on* \mathcal{X} *. Then, for all* $x \in \text{dom } \partial h$ *,* $y \in \mathcal{Y}$ *, we have:*

$$
a) \ \ x = Q(y) \quad \Longleftrightarrow \ y \in \partial h(x). \tag{C.4a}
$$

b)
$$
x^+ = P_x(y) \iff \nabla h(x) + y \in \partial h(x^+) \iff x^+ = Q(\nabla h(x) + y).
$$
 (C.4b)

51 *Finally, if* $x = Q(y)$ *and* $p \in \mathcal{X}$ *, we have*

$$
\langle \nabla h(x), x - p \rangle \le \langle y, x - p \rangle. \tag{C.5}
$$

s Remark. Note that [\(C.4b\)](#page-2-0) directly implies that $\partial h(x^+) \neq \emptyset$, i.e., $x^+ \in \text{dom } \partial h$. An immediate 53 consequence of this is that the update rule $x \leftarrow P_x(y)$ is *well-posed*, i.e., it can be iterated in

⁵⁴ perpetuity.

- 55 *Proof of Lemma 1*. To prove [\(C.4a\)](#page-2-2), note that x solves [\(C.2\)](#page-2-3) if and only if $y \partial h(x) \ni 0$, i.e., if and 56 only if $y \in \partial h(x)$. Similarly, for [\(C.4b\)](#page-2-0), comparing [\(A.2\)](#page-0-3) and [\(C.1\)](#page-2-4), we see that x^+ solves (A.2) if 57 and only if $\nabla h(x) + y \in \partial h(x^+)$, i.e., if and only if $x^+ = Q(\nabla h(x) + y)$.
- For the inequality [\(C.5\)](#page-2-5), it suffices to show it holds for interior $p \in \mathcal{X}^{\circ}$ (by continuity). To do so, let

$$
\phi(t) = h(x + t(p - x)) - [h(x) + \langle y, x + t(p - x) \rangle].
$$
 (C.6)

59 Since h is strongly convex and $y \in \partial h(x)$ by [\(C.4a\)](#page-2-2), it follows that $\phi(t) > 0$ with equality if and

60 only if $t = 0$. Moreover, note that $\psi(t) = \langle \nabla h(x + t(p - x)) - y, p - x \rangle$ is a continuous selection of

61 subgradients of ϕ . Given that ϕ and ψ are both continuous on [0, 1], it follows that ϕ is continuously

 α differentiable and $\phi' = \psi$ on [0, 1]. Thus, with φ convex and $\phi(t) \ge 0 = \phi(0)$ for all $t \in [0, 1]$, we 63 conclude that $\phi'(0) = \langle \nabla h(x) - y, p - x \rangle \ge 0$, from which our claim follows. П

⁶⁴ We continue with some basic relations connecting the Bregman divergence relative to a target point ⁶⁵ before and after a prox step. The basic ingredient for this is a generalization of the law of cosines

⁶⁶ which is known in the literature as the "three-point identity" [\(Chen and Teboulle,](#page-9-4) [1993\)](#page-9-4):

67 **Lemma 2.** Let *h* be a regularizer on X. Then, for all $p \in \mathcal{X}$ and all $x, x' \in \text{dom } \partial h$, we have

$$
D(p, x') = D(p, x) + D(x, x') + \langle \nabla h(x') - \nabla h(x), x - p \rangle.
$$
 (C.7)

⁶⁸ *Proof.* By definition, we get:

$$
D(p, x') = h(p) - h(x') - \langle \nabla h(x'), p - x' \rangle
$$

\n
$$
D(p, x) = h(p) - h(x) - \langle \nabla h(x), p - x \rangle
$$

\n
$$
D(x, x') = h(x) - h(x') - \langle \nabla h(x'), x - x' \rangle.
$$
\n(C.8)

 \Box

⁶⁹ The lemma then follows by adding the two last lines and subtracting the first.

⁷⁰ With all this at hand, we have the following upper and lower bounds:

Proposition 3. Let h be a K-strongly convex regularizer on X, fix some $p \in \mathcal{X}$, and let $x^+ = P_x(y)$ *72 for* $x \in \text{dom } \partial h$, $y \in \mathcal{Y}$ *. Then, we have:*

$$
D(p, x) \ge \frac{K}{2} \|x - p\|^2. \tag{C.9a}
$$

$$
D(p, x^+) \le D(p, x) - D(x^+, x) + \langle y, x^+ - p \rangle \tag{C.9b}
$$

$$
\leq D(p,x) + \langle y, x - p \rangle + \frac{1}{2K} ||y||_*^2 \tag{C.9c}
$$

⁷³ *Proof of* [\(C.9a\)](#page-3-1)*.* By the strong convexity of h, we get

$$
h(p) \ge h(x) + \langle \nabla h(x), p - x \rangle + \frac{K}{2} ||p - x||^2
$$
 (C.10)

- 74 so [\(C.9a\)](#page-3-1) follows by gathering all terms involving h and recalling the definition of $D(p, x)$. \Box
- ⁷⁵ *Proof of* [\(C.9b\)](#page-3-2) *and* [\(C.9c\)](#page-3-3)*.* By the three-point identity [\(C.7\)](#page-2-6), we readily obtain

$$
D(p, x) = D(p, x^{+}) + D(x^{+}, x) + \langle \nabla h(x) - \nabla h(x^{+}), x^{+} - p \rangle,
$$
 (C.11)

⁷⁶ and hence:

$$
D(p, x^{+}) = D(p, x) - D(x^{+}, x) + \langle \nabla h(x^{+}) - \nabla h(x), x^{+} - p \rangle
$$

$$
\leq D(p, x) - D(x^{+}, x) + \langle y, x^{+} - p \rangle,
$$
 (C.12)

- where, in the last step, we used [\(C.5\)](#page-2-5) and the fact that $x^+ = Q(\nabla h(x) + y)$, by [\(C.4b\)](#page-2-0), since $x^+ = P_x(y)$. The above is just [\(C.9b\)](#page-3-2), so the first part of our proof is complete.
-
- ⁷⁹ To proceed with the proof of [\(C.9c\)](#page-3-3), note that [\(C.12\)](#page-3-4) gives

$$
D(p, x+) \le D(p, x) + \langle y, x - p \rangle + \langle y, x+ - x \rangle - D(x+, x).
$$
 (C.13)

⁸⁰ By Young's inequality [\(Rockafellar,](#page-9-3) [1970\)](#page-9-3), we also have

$$
\langle y, x^+ - x \rangle \le \frac{K}{2} \|x^+ - x\|^2 + \frac{1}{2K} \|y\|_{*}^2,
$$
 (C.14)

 \Box

⁸¹ and hence

$$
D(p, x^{+}) \le D(p, x) + \langle y, x - p \rangle + \frac{1}{2K} ||y||_{*}^{2} + \frac{K}{2} ||x^{+} - x||^{2} - D(x^{+}, x)
$$

\n
$$
\le D(p, x) + \langle y, x - p \rangle + \frac{1}{2K} ||y||_{*}^{2},
$$
\n(C.15)

82 with the last step following from [Lemma 1](#page-2-1) after plugging in x in place of p.

83 D Asymptotic convergence analysis

⁸⁴ Our goal in this appendix is to prove [Theorem 5.1.](#page-0-2) Since this is our basic asymptotic convergence ⁸⁵ result, we reproduce it below for convenience:

86 **Theorem.** Suppose that the players of a monotone game $G \equiv G(N, \mathcal{X}, u)$ follow [\(MD-b\)](#page-0-1) with 87 *step-size* γ_n *and query radius* δ_n *such that*

$$
\lim_{n \to \infty} \gamma_n = \lim_{n \to \infty} \delta_n = 0, \quad \sum_{n=1}^{\infty} \gamma_n = \infty, \quad \sum_{n=1}^{\infty} \gamma_n \delta_n < \infty, \quad \text{and} \quad \sum_{n=1}^{\infty} \frac{\gamma_n^2}{\delta_n^2} < \infty. \tag{D.1}
$$

 s ⁸ Then, the sequence of realized actions \hat{X}_n converges to Nash equilibrium with probability 1.

⁸⁹ Our proof strategy will be based on a two-pronged approach. First, we will show that the pivot 90 sequence X_n satisfies a "quasi-Fejér" property [\(Combettes,](#page-9-5) [2001;](#page-9-5) [Combettes and Pesquet,](#page-9-6) [2015\)](#page-9-6) with ⁹¹ respect to the Bregman divergence. This quasi-Fejér property allows us to show that the Bregman 92 divergence $D(x^*, X_n)$ with respect to a Nash equilibrium x^* of G converges. To show that this 93 limit is actually zero for *some* Nash equilibrium, we prove that, with probability 1, the sequence X_n ⁹⁴ admits a (random) subsequence that converges to a Nash equilibrium. The theorem then follows by ⁹⁵ combining these two results.

- ⁹⁶ To carry all this out, we begin with an auxiliary lemma for the simultaneous perturbation stochastic
- ⁹⁷ approximation (SPSA) estimation process of [Section 4:](#page-0-2)
- 98 **Lemma 4.** *The SPSA estimator* $\hat{v} = (\hat{v}_i)_{i \in \mathcal{N}}$ *given by* [\(4.2\)](#page-0-2) *satisfies*

$$
\mathbb{E}[\hat{v}_i] = \nabla_i u_i^{\delta},\tag{D.2}
$$

99 *with* u_i^{δ} as in [\(4.3\)](#page-0-2). Moreover, we have $\|\nabla_i u_i^{\delta} - \nabla_i u_i\|_{\infty} = \mathcal{O}(\delta)$.

Proof. By the independence of the sampling directions z_i , $i \in \mathcal{N}$, we have

$$
\mathcal{E}[\hat{v}_i] = \frac{d_i/\delta}{\prod_j \text{vol}(\mathbb{S}_j)} \int_{\mathbb{S}_1} \cdots \int_{\mathbb{S}_N} u_i(x_1 + \delta z_1, \dots, x_N + \delta z_N) z_i \ dz_1 \cdots dz_N
$$

\n
$$
= \frac{d_i/\delta}{\prod_j \text{vol}(\delta \mathbb{S}_j)} \int_{\delta \mathbb{S}_1} \cdots \int_{\delta \mathbb{S}_N} u_i(x_1 + z_1, \dots, x_N + z_N) \frac{z_i}{\|z_i\|} \ dz_1 \cdots dz_N
$$

\n
$$
= \frac{d_i/\delta}{\prod_j \text{vol}(\delta \mathbb{S}_j)} \int_{\delta \mathbb{S}_i} \int_{\prod_{j \neq i} \delta \mathbb{S}_j} u_i(x_i + z_i; x_{-i} + z_{-i}) \frac{z_i}{\|z_i\|} \ dz_i \ dz_{-i}
$$

\n
$$
= \frac{d_i/\delta}{\prod_j \text{vol}(\delta \mathbb{S}_j)} \int_{\delta \mathbb{B}_i} \int_{\prod_{j \neq i} \delta \mathbb{S}_j} \nabla_i u_i(x_i + w_i; x_{-i} + z_{-i}) \ dw_i \ dz_{-i},
$$
 (D.3)

¹⁰¹ where, in the last line, we used the identity

 \mathbb{F}

$$
\nabla \int_{\delta \mathbb{B}} f(x+w) \, dw = \int_{\delta \mathbb{S}} f(x+z) \frac{z}{\|z\|} \, dz \tag{D.4}
$$

102 which, in turn, follows from Stokes' theorem [\(Flaxman et al.,](#page-9-7) [2005;](#page-9-7) [Lee,](#page-9-8) [2003\)](#page-9-8). Since $\text{vol}(\delta \mathbb{B}_i)$ = 103 (δ/d_i) vol $(\delta\mathbb{S}_i)$, the above yields $\mathbb{E}[\hat{v}_i] = \nabla_i u_i^{\delta}$ with u_i^{δ} given by [\(4.3\)](#page-0-2).

104 For the second part of the lemma, let L_i denote the Lipschitz constant of v_i , i.e., $||v_i(x') - v_i(x)||_* \le$ 105 $L_i||x'-x||$ for all $x, x' \in \mathcal{X}$. Then, for all $w_i \in \delta \mathbb{B}_i$ and all $z_j \in \delta \mathbb{S}_j$, $j \neq i$, we have

$$
\|\nabla_i u_i(x_i + w_i; x_{-i} + z_{-i}) - \nabla_i u_i(x)\| \le L_i \sqrt{\|w_i\|^2 + \sum_{j \ne i} \|z_j\|^2} \le L_i \sqrt{N} \delta. \tag{D.5}
$$

¹⁰⁶ Our assertion then follows by integrating and differentiating under the integral sign.

¹⁰⁷ With this basic estimate at hand, we proceed to establish the convergence of the Bregman divergence ¹⁰⁸ relative to the game's Nash equilibria:

109 **Proposition 5.** Let x^* be a Nash equilibrium of G. Then, with assumptions as in [Theorem 5.1,](#page-0-2) the 110 Bregman divergence $D(x^*, X_n)$ converges (a.s.) to a finite random variable D_{∞} .

111 *Remark.* For expository reasons, we tacitly assume above (and in what follows) that G satisfies [\(DSC\)](#page-0-2) 112 with weights $\lambda_i = 1$ for all $i \in \mathcal{N}$. If this is not the case, the Bregman divergence $D(p, x)$ should be

¹¹³ replaced by the weight-adjusted variant

$$
D^{\lambda}(p,x) = \sum_{i \in \mathcal{N}} \lambda_i D(p_i, x_i).
$$
 (D.6)

 \Box

- ¹¹⁴ Since this adjustment would force us to carry around all player indices, the presentation would ¹¹⁵ become significantly more cumbersome; to avoid this, we stick with the simpler, unweighted case.
- 116 *Proof.* Let $D_n = D(x^*, X_n)$ for some Nash equilibrium x^* of G and write

$$
\hat{v}_n = v(X_n) + U_{n+1} + b_n,\tag{D.7}
$$

117 where, recalling the setup of [Section 4](#page-0-2) in the main body of the paper, the noise process U_{n+1} = 118 $\hat{v}_n - \mathbb{E}[\hat{v}_n | \mathcal{F}_n]$ is an \mathcal{F}_n -adapted martingale difference sequence and $b_n = v^{\delta_n}(X_n^{\delta_n}) - v(X_n)$ 119 denotes the systematic bias of the estimator \hat{v}_n .^{[3](#page-5-0)} Then, by [Proposition 3,](#page-3-5) we have

$$
D_{n+1} = D(x^*, P_{X_n}(\gamma_n \hat{v}_n)) \le D(x^*, X_n) + \gamma_n \langle \hat{v}_n, X_n - x^* \rangle + \frac{\gamma_n^2}{2K} \|\hat{v}_n\|_{*}^2
$$

= $D_n + \gamma_n \langle v(X_n) + U_{n+1} + b_n, X_n - x^* \rangle + \frac{\gamma_n^2}{2K} \|\hat{v}_n\|_{*}^2$

$$
\le D_n + \gamma_n \xi_{n+1} + \gamma_n r_n + \frac{\gamma_n^2}{2K} \|\hat{v}_n\|_{*}^2,
$$
 (D.8)

120 where, in the last line, we set $\xi_{n+1} = \langle U_{n+1}, X_n - x^* \rangle$, $r_n = \langle b_n, X_n - x^* \rangle$, and we used the 121 variational characterization [\(VI\)](#page-0-2) of Nash equilibria of monotone games. Thus, conditioning on \mathcal{F}_n ¹²² and taking expectations, we get

$$
\mathbb{E}[D_{n+1} | \mathcal{F}_n] \le D_n + \mathbb{E}[\xi_{n+1} | \mathcal{F}_n] + \gamma_n \mathbb{E}[r_n | \mathcal{F}_n] + \frac{\gamma_n^2}{2K} \mathbb{E}[\|\hat{v}_n\|_*^2 | \mathcal{F}_n]
$$

\n
$$
\le D_n + \gamma_n \mathbb{E}[r_n | \mathcal{F}_n] + \frac{V^2}{2K} \frac{\gamma_n^2}{\delta_n^2}.
$$
 (D.9)

123 where we set $V^2 = \sum_i d_i^2 \max_{x \in \mathcal{X}} |u_i(x)|^2$ and we used the fact that X_n is \mathcal{F}_n -measurable, so

$$
\mathbb{E}[\xi_{n+1} | \mathcal{F}_n] = \langle \mathbb{E}[U_{n+1} | \mathcal{F}_n], X_n - x^* \rangle = 0.
$$
 (D.10)

¹²⁴ Finally, by [Lemma 4,](#page-4-0) we have

$$
||b_n||_* = ||v^{\delta_n}(X_n^{\delta_n}) - v(X_n)||_* \le ||v^{\delta_n}(X_n^{\delta_n}) - v(X_n^{\delta_n})||_* + ||v(X_n^{\delta_n}) - v(X_n)||_* = \mathcal{O}(\delta_n),
$$
\n(D.11)

where we used the fact that v is Lipschitz continuous and $||v^{\delta} - v||_{\infty} = \mathcal{O}(\delta)$. This shows that there 126 exists some $B > 0$ such that $r_n \leq B\delta_n$; as a consequence, we obtain

$$
\mathbb{E}[D_{n+1} | \mathcal{F}_n] \le D_n + B\gamma_n \delta_n + \frac{V^2}{2K} \frac{\gamma_n^2}{\delta_n^2}.
$$
 (D.12)

127 Now, letting $R_n = D_n + \sum_{k=n}^{\infty} [B\gamma_k \delta_k + (2K)^{-1} V^2 \gamma_k^2 / \delta_k^2]$, the estimate [\(D.8\)](#page-5-1) gives

$$
\mathbb{E}[R_{n+1} | \mathcal{F}_n] = \mathbb{E}[D_{n+1} | \mathcal{F}_n] + \sum_{k=n+1}^{\infty} \left[B\gamma_k \delta_k + \frac{V^2}{2K} \frac{\gamma_k^2}{\delta_k^2} \right]
$$

\n
$$
\leq D_n + B\gamma_n \delta_n + \frac{V^2}{2K} \frac{\gamma_n^2}{\delta_n^2} + \sum_{k=n+1}^{\infty} \left[B\gamma_k \delta_k + \frac{V^2}{2K} \frac{\gamma_k^2}{\delta_k^2} \right]
$$

\n
$$
\leq D_n + \sum_{k=n}^{\infty} \left[B\gamma_k \delta_k + \frac{V^2}{2K} \frac{\gamma_k^2}{\delta_k^2} \right]
$$

\n
$$
= R_n, \tag{D.13}
$$

128 i.e., R_n is an \mathcal{F}_n -adapted supermartingale.^{[4](#page-5-2)} Since the series $\sum_{n=1}^{\infty} \gamma_n \delta_n$ and $\sum_{n=1}^{\infty} \gamma_n^2/\delta_n^2$ are both ¹²⁹ summable, it follows that

$$
\mathbb{E}[R_n] = \mathbb{E}[\mathbb{E}[R_n | \mathcal{F}_{n-1}]] \le \mathbb{E}[R_{n-1}] \le \cdots \le \mathbb{E}[R_1] \le \mathbb{E}[D_1] + \sum_{n=1}^{\infty} \left[B\gamma_n \delta_n + \frac{V^2}{2K} \frac{\gamma_n^2}{\delta_n^2} \right] < \infty
$$
\n(D.14)

130 i.e., R_n is uniformly bounded in L^1 . Thus, by Doob's convergence theorem for supermartingales 131 [\(Hall and Heyde,](#page-9-9) [1980,](#page-9-9) Theorem 2.5), it follows that R_n converges (a.s.) to some finite random 132 variable R_{∞} . In turn, by inverting the definition of R_n , it follows that D_n converges (a.s.) to some 133 random variable D_{∞} , as claimed.

³Recall here that X_i^{δ} , $i \in \mathcal{N}$, denotes the δ -adjusted pivot $X_i^{\delta} = X_i + r_i^{-1} \delta(X_i - p_i)$, i.e., including the feasibility adjustment $r_i^{-1}(X_i - p_i)$.

⁴In particular, this shows that $\mathbb{E}[D_n | \mathcal{F}_{n-1}]$ is quasi-Fejér in the sense of [Combettes](#page-9-5) [\(2001\)](#page-9-5).

¹³⁴ Proposition 6. *Suppose that the assumptions of [Theorem 5.1](#page-0-2) hold. Then, with probability* 1*, there* 135 *exists a (random) subsequence* X_{n_k} of [\(MD-b\)](#page-0-1) which converges to Nash equilibrium.

136 *Proof.* We begin with the technical observation that the set \mathcal{X}^* of Nash equilibria of \mathcal{G} is closed (and hence, compact). Indeed, let x_n^* , $n = 1, 2, \ldots$, be a sequence of Nash equilibria converging to some 138 Limit point $x^* \in \mathcal{X}$; to show that \mathcal{X}^* is closed, it suffices to show that $x^* \in \mathcal{X}$. However, since Nash 139 equilibria of G satisfy the variational characterization [\(VI\)](#page-0-2), we also have $\langle v(x), x - x_n^* \rangle \le 0$ for all 140 $x \in \mathcal{X}$. Hence, with $x_n^* \to x^*$ as $n \to \infty$, it follows that

$$
\langle v(x), x - x^* \rangle = \lim_{n \to \infty} \langle v(x), x - x_n^* \rangle \le 0 \quad \text{for all } x \in \mathcal{X}, \tag{D.15}
$$

141 i.e., x^* satisfies [\(VI\)](#page-0-2). Since G is monotone, we conclude that x^* is a Nash equilibrium, as claimed.

142 Suppose now ad absurdum that, with positive probability, the pivot sequence X_n generated by [\(MD-b\)](#page-0-1) 143 admits no limit points in \mathcal{X}^{*} .^{[5](#page-6-0)} Conditioning on this event, and given that \mathcal{X}^{*} is compact, there exists a (nonempty) compact set $C \subset \mathcal{X}$ such that $C \cap \mathcal{X}^* = \emptyset$ and $X_n \in \mathcal{C}$ for all sufficiently large n. 145 Moreover, by [\(VI\)](#page-0-2), we have $\langle v(x), x - x^* \rangle < 0$ whenever $x \in \mathcal{C}$ and $x^* \in \mathcal{X}^*$. Therefore, by the

146 continuity of v and the compactness of \mathcal{X}^* and C, there exists some $c > 0$ such that

$$
\langle v(x), x - x^* \rangle \le -c \quad \text{for all } x \in \mathcal{C}, x^* \in \mathcal{X}.
$$
 (D.16)

147 To proceed, fix some $x^* \in \mathcal{X}^*$ and let $D_n = D(x^*, X_n)$ as in the proof of [Proposition 5.](#page-4-1) Then, ¹⁴⁸ telescoping [\(D.8\)](#page-5-1) yields the estimate

$$
D_{n+1} \leq D_1 + \sum_{k=1}^n \gamma_k \langle v(X_n), X_n - x^* \rangle + \sum_{k=1}^n \gamma_k \xi_{k+1} + \sum_{k=1}^n \gamma_k r_k + \sum_{k=1}^n \frac{\gamma_k^2}{2K} \|\hat{v}_n\|_{*}^2, \quad (D.17)
$$

¹⁴⁹ where, as in the proof of [Proposition 5,](#page-4-1) we set

$$
\xi_{n+1} = \langle U_{n+1}, X_n - x^* \rangle \tag{D.18}
$$

¹⁵⁰ and

$$
r_n = \langle b_n, X_n - x^* \rangle. \tag{D.19}
$$

151 Subsequently, letting $\tau_n = \sum_{k=1}^n \gamma_k$ and using [\(D.16\)](#page-6-1), we obtain

$$
D_{n+1} \le D_1 - \tau_n \bigg[c - \frac{\sum_{k=1}^n \gamma_k \xi_{k+1}}{\tau_n} - \frac{\sum_{k=1}^n \gamma_k r_k}{\tau_n} - \frac{(2K)^{-1} \sum_{k=1}^n \gamma_k^2 \|\hat{v}_k\|_*^2}{\tau_n} \bigg].
$$
 (D.20)

152 Since U_n is a martingale difference sequence with respect to \mathcal{F}_n , we have $\mathbb{E}[\xi_{n+1} | \mathcal{F}_n] = 0$ (recall 153 that X_n is \mathcal{F}_n -measurable by construction). Moreover, by construction, there exists some constant 154 $\sigma > 0$ such that

$$
||U_{n+1}||_*^2 \le \frac{\sigma^2}{\delta_n^2},
$$
\n(D.21)

¹⁵⁵ and hence:

$$
\sum_{n=1}^{\infty} \gamma_n^2 \mathbb{E}[\xi_{n+1}^2 | \mathcal{F}_n] \le \sum_{n=1}^{\infty} \gamma_n^2 \|X_n - x^*\|^2 \mathbb{E}[\|U_{n+1}\|_*^2 | \mathcal{F}_n]
$$

$$
\le \text{diam}(\mathcal{X})^2 \sigma^2 \sum_{n=1}^{\infty} \frac{\gamma_n^2}{\delta_n^2} < \infty.
$$
 (D.22)

- ¹⁵⁶ Therefore, by the law of large numbers for martingale difference sequences [\(Hall and Heyde,](#page-9-9) [1980,](#page-9-9)
- 157 Theorem 2.18), we conclude that $\tau_n^{-1} \sum_{k=1}^n \gamma_k \xi_{k+1}$ converges to 0 with probability 1.

For the third term in the brackets of [\(D.20\)](#page-6-2) we have $r_n \to 0$ as $n \to \infty$ (a.s.). Since $\sum_{n=1}^{\infty} \gamma_n = \infty$, 159 it follows $\sum_{k=1}^n \gamma_k r_k / \sum_{k=1}^n \gamma_k \to 0$.

⁵We assume here without loss of generality that $\mathcal{X}^* \neq \mathcal{X}$; otherwise, there is nothing to show.

160 Finally, for the last term in the brackets of [\(D.20\)](#page-6-2), let $S_{n+1} = \sum_{k=1}^{n} \gamma_k^2 ||\hat{v}_k||_*^2$. Since \hat{v}_k is \mathcal{F}_n -161 measurable for all $k = 1, 2, \ldots, n - 1$, we have

$$
\mathbb{E}[S_{n+1} | \mathcal{F}_n] = \mathbb{E}\left[\sum_{k=1}^{n-1} \gamma_k^2 \|\hat{v}_k\|_*^2 + \gamma_n^2 \|\hat{v}_n\|_*^2 \middle| \mathcal{F}_n\right] = S_n + \gamma_n^2 \mathbb{E}[\|\hat{v}_n\|_*^2 | \mathcal{F}_n] \ge S_n, \quad (D.23)
$$

162 i.e., S_n is a submartingale with respect to \mathcal{F}_n . Furthermore, by the law of total expectation, we also ¹⁶³ have

$$
\mathbb{E}[S_{n+1}] = \mathbb{E}[\mathbb{E}[S_{n+1} | \mathcal{F}_n]] \le V^2 \sum_{k=1}^n \frac{\gamma_k^2}{\delta_k^2} \le V^2 \sum_{k=1}^\infty \frac{\gamma_k^2}{\delta_k^2} < \infty,\tag{D.24}
$$

164 implying in turn that S_n is uniformly bounded in L^1 . Hence, by Doob's submartingale convergence 165 theorem [\(Hall and Heyde,](#page-9-9) [1980,](#page-9-9) Theorem 2.5), we conclude that S_n converges to some (almost surely 166 finite) random variable S_{∞} with $\mathbb{E}[S_{\infty}] < \infty$. Consequently, we have $\lim_{n\to\infty} S_{n+1}/\tau_n = 0$ with ¹⁶⁷ probability 1.

168 Applying all of the above to the estimate [\(D.20\)](#page-6-2), we get $D_{n+1} \leq D_1 - c\tau_n/2$ for sufficiently large n, 169 and hence, $D(x^*, X_n) \to -\infty$, a contradiction. Going back to our original assumption, this shows that at least one of the limit points of X_n must lie in \mathcal{X}^* , so our proof is complete. □

¹⁷¹ We are finally in a position to prove [Theorem 5.1](#page-0-2) regarding the convergence of [\(MD-b\)](#page-0-1):

Proof of [Theorem 5.1.](#page-0-2) By [Proposition 6,](#page-5-3) there exists a (possibly random) Nash equilibrium x^* of $\mathcal G$ 173 such that $||X_{n_k} - x^*|| \to 0$ for some (random) subsequence X_{n_k} . By the assumed reciprocity of the 174 Bregman divergence, this implies that $\liminf_{n\to\infty} D(x^*, X_n) = 0$ (a.s.). Since $\lim_{n\to\infty} D(x^*, X_n)$ ¹⁷⁵ exists with probability 1 (by [Proposition 5\)](#page-4-1), it follows that

$$
\lim_{n \to \infty} D(x^*, X_n) = \liminf_{n \to \infty} D(x^*, X_n) = 0,
$$
\n(D.25)

176 i.e., X_n converges to x^* by the first part of [Proposition 3.](#page-3-5) Since $\delta_n \to 0$ and $\|\hat{X}_n - X_n\|$ 177 $\delta_n ||W_n|| = \mathcal{O}(\delta_n)$, our claim follows.

178 E Rate of convergence

179 We now turn to the finite-time analysis of [\(MD-b\)](#page-0-1). To begin, we briefly recall that a game $\mathcal G$ is ¹⁸⁰ β*-strongly monotone* if it satisfies the condition

$$
\sum_{i \in \mathcal{N}} \lambda_i \langle v_i(x') - v_i(x), x'_i - x_i \rangle \le -\frac{\beta}{2} ||x - x'||^2 \tag{β-DSC}
$$

181 for some $\lambda_i, \beta > 0$ and for all $x, x' \in \mathcal{X}$. Our aim in what follows will be to prove the following ¹⁸² convergence rate estimate for multi-agent mirror descent in strongly monotone games:

183 **Theorem 7.** Let x^* be the (*unique*) *Nash equilibrium of a β-strongly monotone game. Then:*

¹⁸⁴ *a*) *If the players have access to a gradient oracle satisfying* [\(4.1\)](#page-0-2) *and they follow* [\(MD\)](#page-0-2) *with* 185 *Euclidean projections and step-size sequence* $\gamma_n = \gamma/n$ *for some* $\gamma > 1/\beta$ *, we have*

$$
\mathbb{E}[\|X_n - x^*\|^2] = \mathcal{O}(n^{-1}).
$$
 (E.1)

¹⁸⁶ *b*) *If the players only have bandit feedback and they follow* [\(MD-b\)](#page-0-1) *with Euclidean projections* 187 *and parameters* $\gamma_n = \gamma/n$ *and* $\delta_n = \delta/n^{1/3}$ *with* $\gamma > 1/(3\beta)$ *and* $\delta > 0$ *, we have*

$$
\mathbb{E}[\|\hat{X}_n - x^*\|^2] = \mathcal{O}(n^{-1/3}).\tag{E.2}
$$

¹⁸⁸ *Remark.* [Theorem 5.2](#page-0-2) is recovered by the second part of [Theorem 7](#page-7-0) above; the first part (which was ¹⁸⁹ alluded to in the main paper) serves as a benchmark to quantify the gap between bandit and oracle ¹⁹⁰ feedback.

¹⁹¹ For the proof of [Theorem 7](#page-7-0) we will need the following lemma on numerical sequences, a version of ¹⁹² which is often attributed to [Chung](#page-9-10) [\(1954\)](#page-9-10):

193 **Lemma 8.** Let a_n , $n = 1, 2, \ldots$, be a non-negative sequence such that

$$
a_{n+1} \le a_n \left(1 - \frac{P}{n^p} \right) + \frac{Q}{n^{p+q}} \tag{E.3}
$$

194 *where* $0 < p \le 1$, $q > 0$, and P , $Q > 0$. Then, assuming $P > q$ if $p = 1$, we have

$$
a_n \le \frac{Q}{R} \frac{1}{n^q} + o\left(\frac{1}{n^q}\right),\tag{E.4}
$$

195 *with* $R = P$ *if* $p < 1$ *and* $R = P - q$ *if* $p = 1$ *.*

196 *Proof.* Clearly, it suffices to show that $\limsup_{n\to\infty} n^q a_n \leq Q/R$. To that end, write $q_n = n[(1 +$ 197 $1/n)^{q} - 1$, so $(1 + 1/n)^{q} = 1 + q_n/n$ and $q_n \to q$ as $n \to \infty$. Then, multiplying both sides of [\(E.3\)](#page-8-0) 198 by $(n+1)^q$ and letting $\tilde{a}_n = a_n n^q$, we get

$$
\tilde{a}_{n+1} \le a_n (n+1)^q \left(1 - \frac{P}{n^p} \right) + \frac{Q(n+1)^q}{n^{p+q}}
$$

= $\tilde{a}_n \left(1 + \frac{q_n}{n} \right) \left(1 - \frac{P}{n^p} \right) + \frac{Q(1+q_n/n)}{n^p}$
= $\tilde{a}_n \left[1 + \frac{q_n}{n} - \frac{P}{n^p} + \mathcal{O}\left(\frac{1}{n^{p+1}}\right) \right] + \frac{Q_n}{n^p},$ (E.5)

199 where we set $Q_n = Q(1 + q_n/n)$, so $Q_n \to Q$ as $n \to \infty$. Then, under the assumption that $P > q$ 200 when $p = 1$, [\(E.5\)](#page-8-1) can be rewritten as

$$
\tilde{a}_{n+1} \le \tilde{a}_n \left(1 - \frac{R_n}{n^p} \right) + \frac{Q_n}{n^p},\tag{E.6}
$$

- 201 for some sequence R_n with $R_n \to R$ as $n \to \infty$.
- 202 Now, fix some small enough $\varepsilon > 0$. From [\(E.6\)](#page-8-2), we readily get

$$
\tilde{a}_{n+1} \le \tilde{a}_n - \frac{R_n \tilde{a}_n - Q_n}{n^p}.
$$
\n(E.7)

- 203 Since $R_n \to R$ and $Q_n \to Q$ as $n \to \infty$, we will have $R_n > R \varepsilon$ and $Q_n < Q + \varepsilon$ for all n
- 204 greater than some n_{ε} . Thus, if $n \ge n_{\varepsilon}$ and $(R \varepsilon)\tilde{a}_n (Q + \varepsilon) > \varepsilon$, we will also have

$$
\tilde{a}_{n+1} \le \tilde{a}_n - \frac{R_n \tilde{a}_n - Q_n}{n^p} \le \tilde{a}_n - \frac{(R - \varepsilon)\tilde{a}_n - (Q + \varepsilon)}{n^p} \le \tilde{a}_n - \frac{\varepsilon}{n^p}.
$$
 (E.8)

205 The above shows that, as long as $\tilde{a}_n > (Q+2\varepsilon)/(R-\varepsilon)$, \tilde{a}_n will decrease at least by ε/n^p at each step.

206 In turn, since $\sum_{n=1}^{\infty} (1/n^p) = \infty$, it follows by telescoping that $\limsup_{n\to\infty} \tilde{a}_n \leq (Q+2\varepsilon)/(R-\varepsilon)$. 207 Hence, with ε arbitrary, we conclude that $\limsup_{n\to\infty} a_n n^q \leq Q/R$, as claimed.

²⁰⁸ *Proof of [Theorem 7.](#page-7-0)* We begin with the second part of the theorem; the first part will follow by ²⁰⁹ setting some estimates equal to zero, so the analysis is more streamlined that way. Also, as in the 210 previous section, we tacitly assume that (β [-DSC\)](#page-7-1) holds with weights $\lambda_i = 1$ for all $i \in \mathcal{N}$. If this 211 is not the case, the Bregman divergence $D(p, x)$ should be replaced by the weight-adjusted variant ²¹² [\(D.6\)](#page-4-2), but this would only make the presentation more difficult to follow, so we omit the details.

²¹³ The main component of our proof is the estimate [\(D.8\)](#page-5-1), which, for convenience (and with notation as ²¹⁴ in the previous section), we also reproduce below:

$$
D_{n+1} \le D_n + \gamma_n \langle v(X_n), X_n - x^* \rangle + \gamma_n \xi_{n+1} + \gamma_n r_n + \frac{\gamma_n^2}{2K} ||\hat{v}_n||_*^2.
$$
 (E.9)

215 In the above, since the algorithm is run with Euclidean projections, $D_n = \frac{1}{2} ||X_n - x^*||^2$; other 216 than that, ξ_n and r_n are defined as in [\(D.18\)](#page-6-3) and [\(D.19\)](#page-6-4) respectively. Since the game is β-strongly 217 monotone and x^* is a Nash equilibrium, we further have

$$
\langle v(X_n), X_n - x^* \rangle \le \langle v(X_n) - v(x^*), X_n - x^* \rangle \le -\frac{\beta}{2} \|X_n - x^*\|^2 = -\beta D_n,
$$
 (E.10)

²¹⁸ so [\(E.9\)](#page-8-3) becomes

$$
D_{n+1} \le (1 - \beta \gamma_n) D_n + \gamma_n \xi_{n+1} + \gamma_n r_n + \frac{\gamma_n^2}{2K} ||\hat{v}_n||_*^2.
$$
 (E.11)

219 Thus, letting $\overline{D}_n = \mathbb{E}[D_n]$ and taking expectations, we obtain

$$
\bar{D}_{n+1} \le (1 - \beta \gamma_n) \bar{D}_n + B \gamma_n \delta_n + \frac{V^2}{2K} \frac{\gamma_n^2}{\delta_n^2},
$$
\n(E.12)

- 220 with B and V defined as in the proof of [Theorem 5.1](#page-0-2) in the previous section.
- 221 Now, substituting $\gamma_n = \gamma/n^p$ and $\delta_n = \delta/n^q$ in [\(E.12\)](#page-9-11) readily yields

$$
\bar{D}_{n+1} \le \left(1 - \frac{\beta \gamma}{n^p}\right) \bar{D}_n + \frac{B \gamma \delta}{n^{p+q}} + \frac{V^2 \gamma^2 \delta^2}{2Kn^{2(p-q)}}.
$$
\n(E.13)

222 Hence, taking $p = 1$ and $q = 1/3$, the last two exponents are equated, leading to the estimate

$$
\bar{D}_{n+1} \le \left(1 - \frac{\beta \gamma}{n}\right) \bar{D}_n + \frac{C}{n^{4/3}},\tag{E.14}
$$

- 223 with $C = \gamma \delta B + (2K)^{-1} \gamma^2 \delta^2 V^2$. Thus, with $\beta \gamma > 1/3$, applying [Lemma 8](#page-7-2) with $p = 1$ and 224 $q = 1/3$, we finally obtain $\overline{D}_n = \mathcal{O}(1/n^{1/3})$.
- ²²⁵ The proof for the oracle case is similar: the key observation is that the bound [\(E.12\)](#page-9-11) becomes

$$
\bar{D}_{n+1} \le (1 - \beta \gamma_n) \bar{D}_n + \frac{V^2}{2K} \gamma_n^2, \tag{E.15}
$$

226 with V defined as in [\(4.1\)](#page-0-2). Hence, taking $\gamma_n = \gamma/n$ with $\beta \gamma > 1$ and applying again [Lemma 8](#page-7-2) with 227 $p = q = 1$, we obtain $\overline{D}_n = \mathcal{O}(1/n)$ and our proof is complete. П

228 To conclude, we note that the $O(1/n^{1/3})$ bound of [Theorem 7](#page-7-0) cannot be readily improved by 229 choosing a different step-size schedule of the form $\gamma_n \propto 1/n^p$ for some $p < 1$. Indeed, applying 230 [Lemma 8](#page-7-2) to the estimate [\(E.13\)](#page-9-12) yields a bound which is either $O(1/n^q)$ or $O(1/n^{p-2q})$, depending ²³¹ on which exponent is larger. Equating the two exponents (otherwise, one term would be slower than 232 the other), we get $q = p/3$, leading again to a $\mathcal{O}(1/n^{1/3})$ bound. Unless one has finer control on the ²³³ bias/variance of the SPSA gradient estimator used in [\(MD-b\)](#page-0-1), we do not see a way of improving this ²³⁴ bound in the current context.
